

## Working with Multiple Files in Python

- ◆ As your project grows, you will need to split your code into modules.
- ◆ A **module** is a Python file that contains definitions and statements.
- ◆ Each Python file is considered a module.
- ◆ You can import these modules into your main program and into other modules to have access to the elements defined within them, while still keeping your program organized and compartmentalized.
- ◆ When you import a module, Python creates an object representing that module in memory.
- ◆ There are multiple ways to import a module. You can import all the elements it defines or import specific elements (e.g. variables, functions, and classes).
- ◆ Import statements are typically written at the top of the file.

### Import Statements (General Syntax)

These are different alternatives for writing import statements. The name of the module is represented as `<module>` and the imported element is represented as `<element>`.

Import Statement	To Access the Element
<code>import &lt;module&gt;</code>	<code>&lt;module&gt;.&lt;element&gt;</code>
<code>from &lt;module&gt; import &lt;element&gt;</code>	<code>&lt;element&gt;</code>
<code>from &lt;module&gt; import *</code>	<code>&lt;element&gt;</code>
<code>import &lt;module&gt; as &lt;name&gt;</code>	<code>&lt;name&gt;.&lt;element&gt;</code>

### Import Statements (Examples)

If you need to import the `foo()` function from a custom module named `my_module`, these are some alternatives:

Import Statement	To Call <code>foo()</code>
<code>import my_module</code>	<code>my_module.foo()</code>
<code>from my_module import foo()</code>	<code>foo()</code>
<code>from my_module import *</code>	<code>foo()</code>
<code>import my_module as <b>module_alias</b></code>	<code><b>module_alias</b>.foo()</code>
